

Cocreating with AI: LLMs as data scientist agents

Hamburg May 28 2025

**Data Analysis
Using AI**

4.4.4 LLMs as programming assistant for Python

As outlined in Chapter [1.3.15](#), Large Language Models (LLMs) are valuable tools for coding assistance, particularly with languages like Python, where they have shown considerable efficacy. Suppose we are in the Python environment within Stata, having imported the variable 'ybirth' using the `sfi` module. We seek to perform further computations on this data and are turning to Python programming for assistance. We cannot assure that the prompts and requests demonstrated here will be effective with every LLM or under all circumstances, but we will point out several key features of the prompt that have helped us in the past to get better results:

I am working with the already existing variable ybirth and I want to calculate its mean in Python without any additional modules. The code should all be put into one code section, simple, well-commented, and easy to understand, and reusable. It is important that it is efficient and follows best practices. The goal is to create a solid foundation for analysis that can be easily understood and adapted by others.

data analysis, analytic iteration, design thinking, reproducibility, systems engineering

Abstract

The field of data science currently enjoys a broad definition that includes a wide array of activities which borrow from many other established fields of study. Having such a vague characterization of a field in the early stages might be natural, but over time maintaining such a broad definition becomes unwieldy and impedes progress. In particular, the teaching of data science is hampered by the seeming need to cover many different points of interest. Data scientists must ultimately identify the core of the field by determining what makes the field unique and what it means to develop new knowledge in data science. In this review we attempt to distill some core ideas from data science by focusing on the iterative process of data analysis and develop some generalizations from past experience. Generalizations of this nature could form the basis of a theory of data science and would serve to unify and scale the teaching of data science to large audiences.

Abstract

While there is a widespread belief that artificial general intelligence (AGI) – or even super-human AI – is imminent, complex problems in expert domains are far from being solved. We argue that such problems require human-AI cooperation and that the current state of the art in generative AI is unable to play the role of a reliable partner due to a multitude of shortcomings, including inability to keep track of a complex solution artifact (e.g., a software program), limited support for versatile human preference expression and lack of adapting to human preference in an interactive setting. To address these challenges, we propose HAI-Co², a novel human-AI co-construction framework. We formalize HAI-Co² and discuss the difficult open research problems that it faces. Finally, we present a case study of HAI-Co² and demonstrate its efficacy compared to monolithic generative AI models.

1 Introduction

Despite the impressive achievements of generative AI spearheaded by Large Language Models (LLMs), Language Models and code models (Lozhkov et al., 2024; Wang et al., 2021), multiple recent investi

*Shared senior authorship

Tukey defined data analysis as “procedures for **analyzing data**, techniques for **interpreting the results** of such procedures, ways of planning the **gathering of data** to make its analysis easier, more precise or more accurate, and all the machinery and results of (mathematical) statistics which apply to analyzing data” ([**Tukey 1962**](#), p. 2)

The Excitement

Tukey defined data analysis as
“procedures for **analyzing data**,
techniques for interpreting the results of such procedures,
ways of planning the gathering of data to make its analysis
easier, more precise or more accurate, and all the
machinery and results of (mathematical) statistics which
apply to analyzing data” (Tukey 1962, p. 2)

AI analyzing data

I want to use the Titanic dataset to explore with my students that question whether females and children were prioritized in being saved in the Titanic accident. Can you load the data and show me how to do this in Stata?

Yes! The Titanic dataset is a great resource for exploring whether women and children were prioritized in survival. I'll guide you through loading the dataset and conducting the analysis in Stata.

Step 1: Load the Dataset in Stata

You can download the Titanic dataset from sources like Kaggle or use Stata's built-in datasets (if available). The dataset typically includes variables such as:

- sex: Male or Female
- age: Age of the passenger

If you have a CSV file (e.g., titanic.csv), load it into Stata using:

```
import delimited "titanic.csv", clear
```

Step 2: Check the Data

Verify that your dataset loaded correctly:

```
describe  
list survived sex age if _n <= 10 //  
Preview first 10 rows
```

If age has missing values, check:

```
sum age, detail
```

Step 3: Analyze Survival Rates

To explore whether women and children were prioritized, we can compare

2. Compare Survival by Age (Defining "Children")

First, create a variable for children (e.g., age < 18):

```
gen child = age < 18
```

Then check survival by gender and child status:

```
tab child survived, col  
tab sex child survived, col
```

3. Logistic Regression: Were Women and Children More Likely to Survive?

A logistic regression can help quantify the likelihood of survival:

4. Interaction Between Gender and Being a Child

To check if the effect of being a child differs by gender:

```
logit survived i.sex##i.child i.pclass
```

Step 4: Interpret Results

- If the coefficient for sex is positive and significant, women had higher odds of survival.
- If child has a positive coefficient, children were prioritized.

AI analyzing data

What refinement should I do?

Good question! Here are some refinements that could improve your analysis:

1. Adjust for Socioeconomic Status (Passenger Class)

- We know that **passenger class (pclass)** played a major role in survival.
- Higher-class passengers had better access to lifeboats.

Refinement: Add pclass as a Control Variable

Modify your logistic regression to adjust for class differences:

```
logit survived i.sex##i.child i.pclass
```

- This helps separate the effects of

Refinement: Visualize Survival by Class

```
graph bar (mean) survived, over(sex) over(child) over(pclass), blabel(bar)
```

- This helps you see if class influenced survival within each group.

2. Consider Non-Linearity in Age Effects

Instead of a simple **child vs. adult** binary, age could have a more **gradual effect**.

Refinement: Use Age as a Continuous Variable

```
logit survived i.sex c.age i.pclass
```

- Here, `c. age` treats age as a continuous variable.
- Check whether the effect of age on survival is linear

Refinement: Check for a Nonlinear Effect (Quadratic Term)

```
gen age2 = age^2  
logit survived i.sex c.age c.age2  
i.pclass
```

- If `age2` is significant, age has a **curved** effect on survival.

3. Interaction Between Age and Class

- Were **children in lower classes** at a disadvantage?
- Test if the effect of being a child varies by class.

Refinement: Interaction Between Child and Class

```
logit survived  
i.sex##i.child##i.pclass
```

- This tests if **children in 3rd class had lower survival than children in 1st class**.

Refinement: Marginal Effects by Class

```
margins child#pclass  
marginsplot, xlabel(1 "1st Class" 2  
"2nd Class" 3 "3rd Class")
```

- This shows survival rates for **children vs. adults across classes**.

Tukey defined data analysis as “procedures for analyzing data, techniques for interpreting the results of such procedures, ways of planning the **gathering of data** to make its analysis easier, more precise or more accurate, and all the machinery and results of (mathematical) statistics which apply to analyzing data” (Tukey 1962, p. 2)

Feb 11, 2023

3 key moments in this video ▾

1. **On a scale of 1-10, how satisfied were you with this class?**
2. **How relevant and useful did you find the content of the class for your academic and/or professional goals?**
(1 = Not relevant at all, 10 = Extremely relevant)
3. **How effective was the instructor in delivering the course material?**
(1 = Not effective at all, 10 = Extremely effective)
4. **How encouraged did you feel to participate and engage in class discussions?**
(1 = Not encouraged at all, 10 = Highly encouraged)

Improve this question “On a scale of 1-10, how satisfied were you with this class?”
Follow the textbook from Schuman and Presser.
Structure output “Revised Question:” “Answer Options:” and Explanation

Revised Question: How would you describe your overall satisfaction with this class?

Answer Options: Very dissatisfied, Dissatisfied, Neutral, Satisfied, Very satisfied.

Explanation: A 5-point scale simplifies the choices and captures nuanced feelings.

Avoiding numbers ensures that participants don't just choose a 'middle' number without giving it thought.

And this one: “How relevant and useful did you find the content of the class for your academic and/or professional goals? (1 = Not relevant at all, 10 = Extremely relevant)”

How would you rate the relevance of the class content to your academic or professional goals?

Answer Options: Not at all relevant, Slightly relevant, Moderately relevant, Very relevant, Extremely relevant.

Explanation: Splitting relevance and usefulness makes it clearer and avoids confusion. Simplified options provide clarity.

Abstract

We propose and explore the possibility that language models can be studied as effective proxies for specific human subpopulations in social science research. Practical and research applications of artificial intelligence tools have sometimes been limited by problematic biases (such as racism or sexism), which are often treated as uniform properties of the models. We show that the “algorithmic bias” within one such tool—the GPT-3 language model—is instead both fine-grained and demographically correlated, meaning that proper conditioning will cause it to accurately emulate response distributions from a wide variety of human subgroups. We term this property *algorithmic fidelity* and explore its extent in GPT-3. We create “silicon samples” by conditioning the model on thousands of sociodemographic backstories from real human participants in multiple large surveys conducted in the United States. We then compare the silicon and human samples to demonstrate that the

Kim, J., Byungkyu, L., (2023, Nov 11). *AI-Augmented Surveys: Leveraging Large Language Models and Surveys for Opinion Prediction* <https://arxiv.org/abs/2305.09620>

DATA: 68,846 individuals' responses to 3,110 questions collected for 33 repeated cross-sectional data between 1972 and 2021 for fine-tuning the LLMs. Retrieved text content of GSS survey questions from GSS data explorer

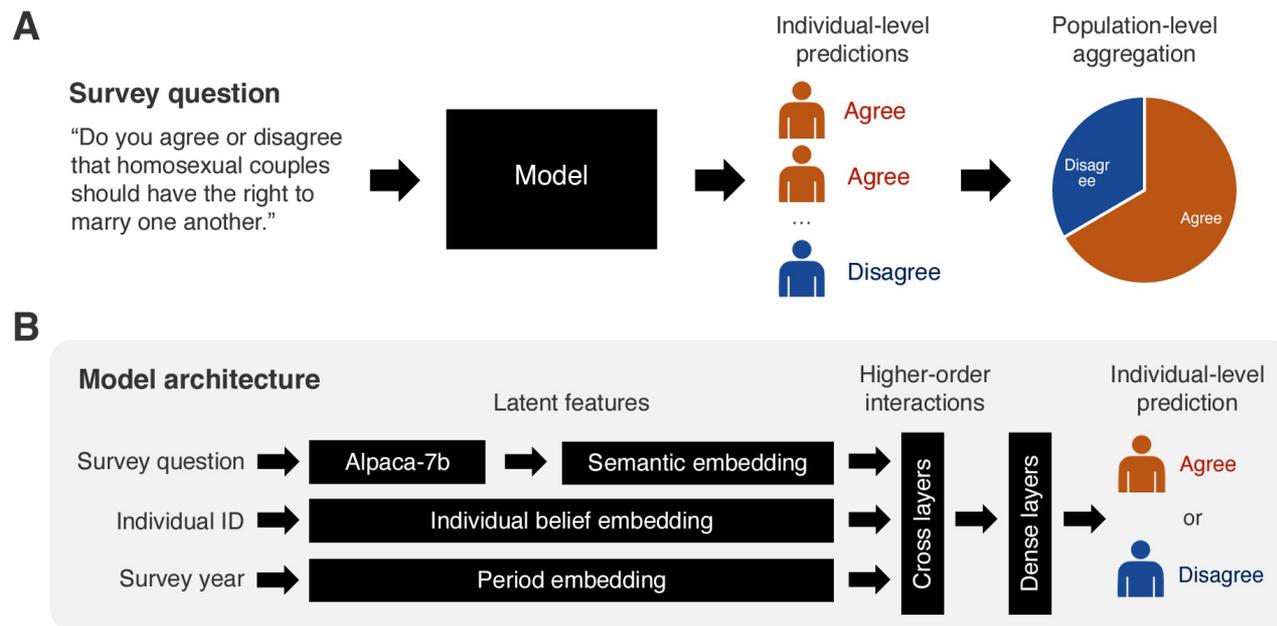

Figure 2: An overview of our methodological framework. In Panel A, we use survey weights when aggregating individual-level prediction into population-level estimates to account for potential sampling bias. In Panel B, individual belief and period embeddings are initially randomly assigned but optimized during the fine-tuning process using dense and cross layers. Semantic embedding, initially estimated by pre-trained LLMs (e.g., Alpaca-7b), is also optimized during the fine-tuning stage.

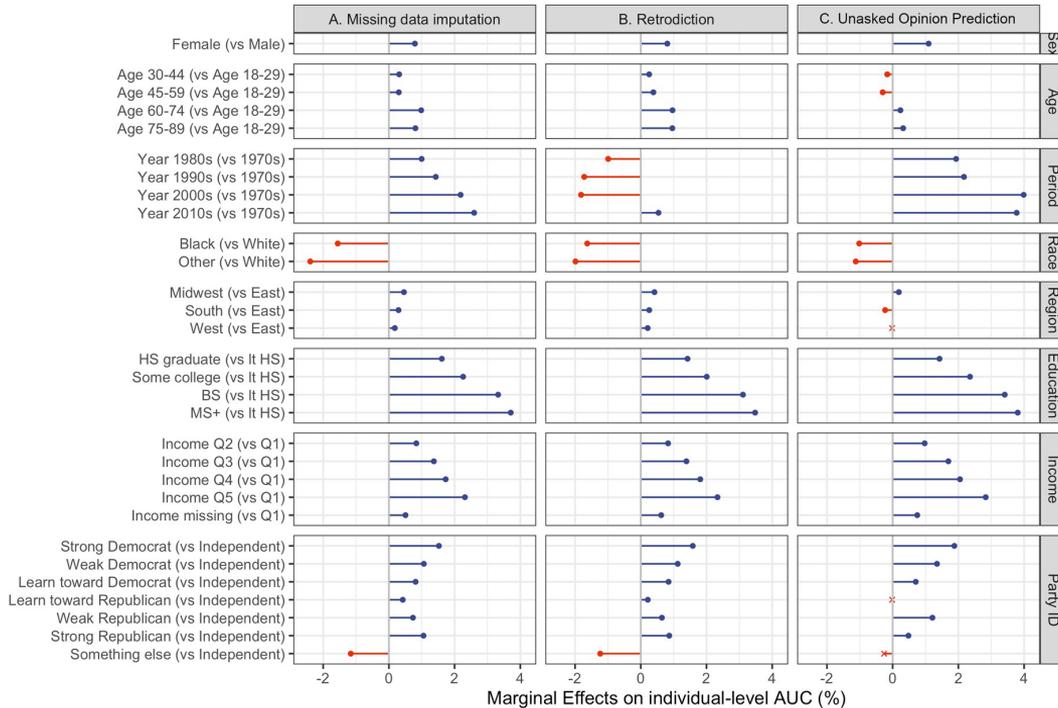

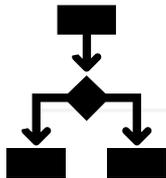

Figure 5: Coefficient plots from OLS regression models predicting individual-level AUC across three different types of missing response prediction. A higher AUC value indicates

For instance, rather than asking the same ten questions to a thousand participants, pollsters can disseminate twenty questions among the same thousand participants, each answering ten questions, and employ the model to **infer individual responses to the remaining ten unasked questions.** On the other hand, given our model's remarkable ability to mimic human responses, even including biases, researchers can use it to **refine their survey questions by systematically examining characteristics of questions that cannot be accurately predicted** (e.g., poor question wording).

Tukey defined data analysis as “procedures for analyzing data, techniques for **interpreting the results** of such procedures, ways of planning the gathering of data to make its analysis easier, more precise or more accurate, and all the machinery and results of (mathematical) statistics which apply to analyzing data” (Tukey 1962, p. 2)

Summary

People earn a living a multitude of ways which is why the occupations they pursue are almost as diverse as people themselves. This makes quantitative analyses of free-text occupational responses from surveys hard to impossible, especially since people may refer to the same occupations with different terms. To address this problem, a variety of different classifications have been developed, such as the International Standard Classification of Occupations 2008 (ISCO) (ILO, 2012) and the German Klassifikation der Berufe 2010 (KldB) (Bundesagentur für Arbeit, 2011), narrowing down the amount of occupation categories into more manageable numbers in the mid hundreds to low thousands and introducing a hierarchical ordering of categories. This leads to a different problem, however: Coding occupations into these standardized categories is usually expensive, time-intensive and plagued by issues of reliability.

Here we present a new instrument that implements a faster, more convenient and interactive occupation coding workflow where respondents are included in the coding process. Based on the respondent's answer, a novel machine learning algorithm generates a list of suggested occupational categories from the Auxiliary Classification of Occupations (Schierholz, 2018), from which one is chosen by the respondent (see Figure 1). Issues of ambiguity within occupational categories are addressed through clarifying follow-up questions. We provide a comprehensive toolbox including anonymized German training data and pre-trained models without raising privacy issues, something not possible yet with other algorithms due to the difficulties of anonymizing free-text data.

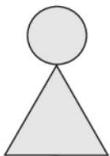

Statement of Need

Assigning occupations to standardized codes is a critical task frequently encountered in research, public administration and beyond: They are used in government censuses (e.g. USA, UK, Germany) and administrative data to better understand economic activity, in epidemiology to estimate exposure to health hazards, and in sociology to obtain a person's socio-economic

ISCO-08: 5141
KldB (2010): 823

The Challenge

You are a software developer who writes python codes from a given set of specifications of the software. Following conditions should be strictly met:

- 1) Every class/method should be fully implemented.
- 2) There should not be any 'pass' statements.
- 3) The packages required should be listed at the end.

Given the following specification, help me write a software in Python that simulates a double pendulum:
list of specifications

Below is the Python code implementation based on the given specifications. Please note that this code is a high-level representation and does not include the actual physics calculations or visualization implementations. Those would require more detailed algorithms and possibly third-party libraries.

Partial codes with placeholder classes

(a) Fails to follow user preference

It is throwing the following error: *Error message*

It appears that there's an incomplete line in the code I provided earlier. The error you're encountering is due to the fact that the code is trying to add a `float` and a `Namespace` object, which is not a valid operation.

Provides new code

The code completed without any error, but no simulation was generated.

I apologize for the oversight. The code provided earlier sets up the simulation and solves the equations of motion but does not include the part that generates the animation.

Provides new code

(b) Unreliable refinement of modular & complex artifact

class Visualization:

```
...
def displayPendulumMotion(self, data_storage):
    # Unpack data
    time_steps = data_storage.time_steps
    angles = data_storage.angles
    ...
```

```
def animate(i):
    # Assuming the length of
    both arms is 1 for simplicity
    x1 = 1 * np.sin(angles[i][0])
    y1 = -1 * np.cos(angles[i][0])
    x2 = x1 + 1 * np.sin(angles[i][1])
    y2 = y1 - 1 * np.cos(angles[i][1])
    ...
```

Human-edits are just another context!

```
l1, l2 = data_storage.arm_lengths
def animate(i):
    # Assuming the length of
    both arms is 1 for simplicity
    x1 = l1 * np.sin(angles[i][0])
    y1 = -l1 * np.cos(angles[i][0])
    x2 = x1 + l2 * np.sin(angles[i][1])
    y2 = y1 - l2 * np.cos(angles[i][1])
```

(c) Unaware of active human participation

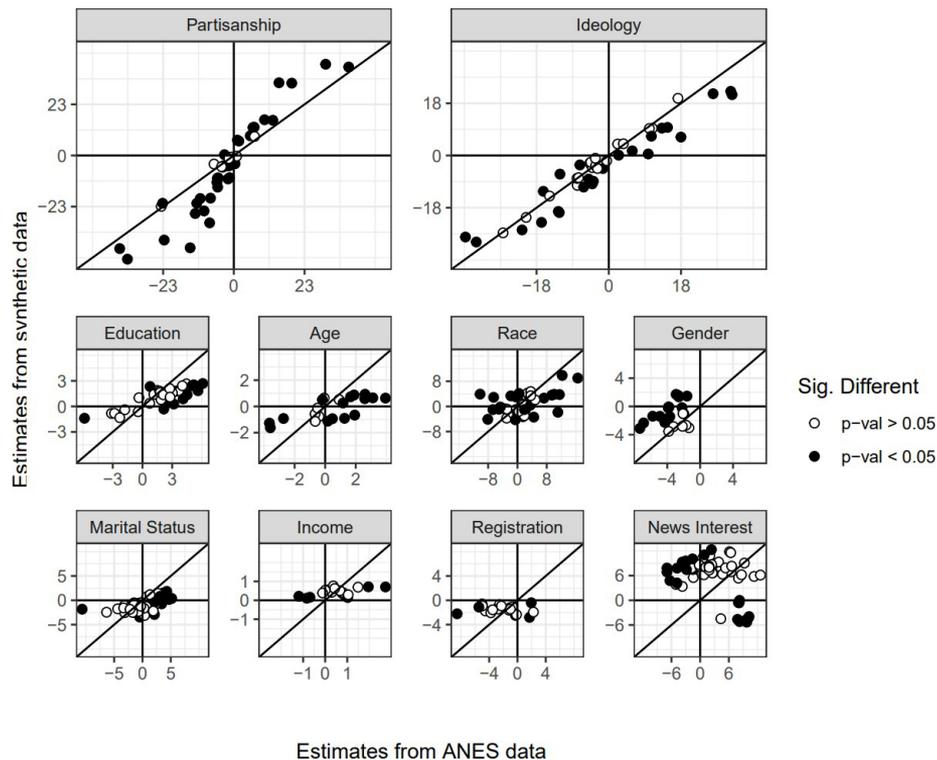

Figure 3: Each point describes the coefficient estimate capturing the partial correlation between a covariate and a feeling thermometer score toward one of the target groups, estimated in either 2016 or 2020. The x-axis position is the coefficient estimated in the ANES data, and the y-axis position is the same coefficient estimated in the synthetic data. Solid points indicate coefficients who are significantly different when estimated in either the ANES or synthetic data, while hollow points are coefficients that are not significantly different. Points in the northeast and southwest quadrants generate the same substantive interpretations, while those in the northwest and southeast quadrants produce differing interpretations. A synthetic dataset that is able to perfectly recover relationships estimated in the ANES data would have all points falling along the 45 degree line.

Bisbee, J., Clinton, J., Dorff, C., Kenkel, B., & Larson, J. (2023, May 4). Synthetic Replacements for Human Survey Data? The Perils of Large Language Models. <https://doi.org/10.31235/osf.io/5ecfa>

English (translation) I am 28 years old and female. I have a college degree, a medium monthly net household income, and am working. I am not religious. Ideologically, I am leaning center-left. I rather weakly identify with the Green party. I live in West Germany. I think the government should facilitate immigration and take measures to reduce income disparities. Did I vote in the 2017 German parliamentary elections and if so, which party did I vote for? I [INSERT]

Notes: We decided not to include “gewählt” (voted) as a suffix in the prompt, using the [MASK] instead of [INSERT] request, as it might bias the output against non-voters by reducing the likelihood of GPT completing the sentence with “nicht” (not) or “ungültig” (invalid) due to German semantics. We leave the further exploration of these effects to prompt engineering researchers.

The (missing) Data Science Theory

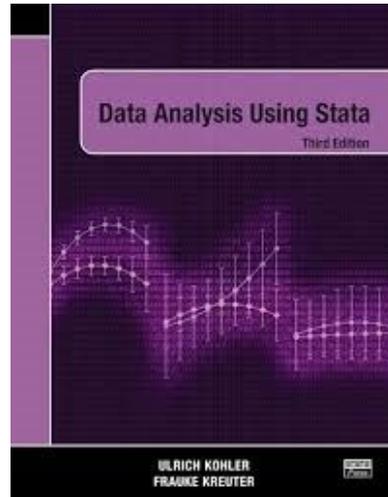

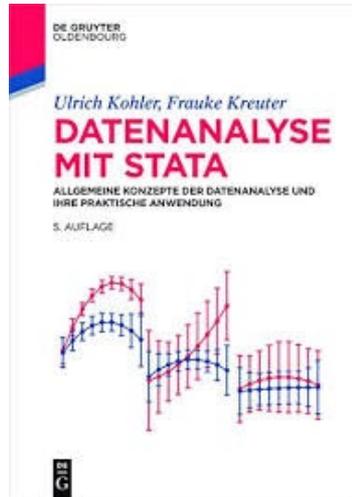

Research Questions

- 1 What data science steps should the agent **be aware of**?
- 2 How can we **enable an agent to ask clarification questions** that address the cognitive biases a human expert may have?
- 3 How can we **evaluate the suitability of the agent-expert dialog efficiently** with sparse data?
